Deadline: 16.03.2017

Exercise 1 – 10 points

<i>das</i>		<i>Haus</i>		<i>ist</i>		<i>klein</i>	
<i>e</i>	<i>t(e f)</i>	<i>e</i>	<i>t(e f)</i>	<i>e</i>	<i>t(e f)</i>	<i>e</i>	<i>t(e f)</i>
<i>the</i>	0.7	<i>house</i>	0.8	<i>is</i>	0.8	<i>small</i>	0.4
<i>that</i>	0.15	<i>building</i>	0.16	<i>'s</i>	0.16	<i>little</i>	0.4
<i>which</i>	0.075	<i>home</i>	0.02	<i>exists</i>	0.02	<i>short</i>	0.1
<i>who</i>	0.05	<i>household</i>	0.015	<i>has</i>	0.015	<i>minor</i>	0.06
<i>this</i>	0.025	<i>shell</i>	0.005	<i>are</i>	0.005	<i>petty</i>	0.04

Given the translation tables above, compute explicitly the translation probability for each of the following translations of the German sentence *das Haus ist klein* (assume the most likely alignment under IBM Model 1):

1. *the house is small*
2. *the house is little*
3. *small house the is*
4. *the*

Answer the following questions:

- a. Is the IBM Model 1 by itself a good model for finding the best translation?
- b. Explain how the noisy-channel model compensates for some of the problems of IBM Model 1 as a translation model.

1 Exercise 2 – 10 points

Consider the following toy example of the alignment problem. Assume we have two pairs of English-French translations:

- (1) (*blue house*, *maison bleue*)
- (2) (*the house*, *la maison*)

Compute the first step of the Expectation-Maximization algorithm on these data to estimate translation probabilities for IBM model 1 (for simplicity, do not consider alignments to the empty word NULL). More precisely, start by assigning uniform values to translation parameters $t(f|e)$. Then calculate the probabilities of all possible alignments $p(a|e, f)$ for these sentences (E-step) and the updated translation probabilities (M-step). Provide the details of your calculations, including the formula.
